ROASTING SYSTEM

5

BACKGROUND OF THE INVENTION

Roasting apparatus for roasting a variety of materials including fresh or green coffee beans is known. The taste and fragrance of coffee depend largely on how and the degree to which the coffee beans have been roasted and how quickly, following roasting, the beans are consumed by brewing coffee with them. It is desirable to produce roasted coffee beans that are consistent in taste and fragrance and in a manner that minimizes storage times to optimize the taste of fresh coffee.

15

Presently, to ensure proper roasting, an experienced roastmaster commonly roasts green coffee beans at a central location for distribution to multiple destinations for sale and consumption.

20

25

30

35

Since coffee beans are presently roasted at a central plant for sale at multiple retail locations, such as supermarkets, stores, and specialty shops, as well as coffee and espresso bars, the roasted beans must be stored and shipped before they reach the consumer. This is in and of itself time-consuming and costly. In addition, for cost and transportation reasons it is not feasible to effectively distribute coffee that is roasted on a given day for sale at the various retail establishments on the same day. Thus, coffee beans presently for sale at retail establishments are seldom fresh and, typically, they are several days to several weeks old before they reach the consumer. This compromises the quality, and especially the aroma, of the coffee and, additionally, increases its cost because of the need to make relatively many deliveries from the roasting plant to the retail locations. Attempts to retain the freshness of roasted coffee beans by, for example, placing them in vacuum bags following roasting do not in fact materially prolong the shelf life of the coffee beans or prevent a deterioration of their

aroma if the roasted beans are stored for any length of time before they are consumed.

Present-day roasting techniques have additional problems. Since roasting takes place at relatively high temperatures, typically in the vicinity of about 500°F (about 260°C), large amounts of smoke and other byproducts are generated, such as white plume smoke, hydrocarbons, and volatile organic compounds ("VOCs") that pollute the atmosphere unless the exhaust gases are first cleaned. This requires an expensive and energy-consuming afterburner that is normally built into the exhaust gas stack for the roasting machine extending through the surrounding wall or ceiling so that the vented exhaust gases are reasonably clean and non-polluting.

The installation and maintenance of exhaust gas venting and scrubbing equipment is relatively expensive and requires modifications to the building. As a result, roasting coffee at individual retail locations has not previously been seriously considered. Instead, the equipment is installed in a few, relatively large roasting plants where the associated costs can be amortized over a relatively large volume of beans that is being roasted for distribution to and sale at many retail locations. Roasting coffee beans at individual retail locations is further unfeasible because of the need to have the roasting process supervised by an experienced roastmaster. The daily roasted coffee bean sales volume is typically too small to justify the high cost of a roastmaster.

As a result of all the foregoing, coffee is today roasted and distributed in practically the same manner as this was done for a very long time. However, the taste and aroma of coffee beans would be greatly improved if it were possible to roast the beans efficiently at the point of sale to the consumer, rather than at a remote, central plant, and the cost of coffee would be reduced if the need for a roasted coffee bean distribution system could be eliminated and coffee beans could be roasted without the supervision of an experienced roastmaster. The cost of coffee to the consumer could then be

decreased and/or the profit margin for the coffee roaster and retailer could be increased.

The present invention, as further described below, achieves these goals while assuring a constant, uniform
 5 roasting of the beans, resulting in the desired constant and uniform aroma.

SUMMARY OF THE INVENTION

The roasting method and apparatus of the present
 10 invention is sufficiently inexpensive to build, install and operate so that it can be used at individual roasted coffee bean retail locations such as supermarkets, coffee shops, and the like. It cleans the hot air used for roasting and cools
 15 it to about room temperature so that the air can be discharged into interior locations, e.g. the interior of a store, without causing indoor pollution or undue heating. It requires no exhaust gas discharge to the outside of the building, it requires no afterburners to eliminate pollutants, and it roasts the coffee beans automatically without requiring the
 20 supervision of an experienced roastmaster.

A principal feature of the present invention therefore is that the roasting of beans, nuts and the like, and in particular of coffee beans, is automated and no longer relies on the subjective judgment of a roastmaster to
 25 determine how and when the beans have reached the desired aroma, flavor, and quality (hereinafter usually "aroma") and the roasting has to be terminated. This is achieved by continuously observing a measurable characteristic or parameter of the beans, preferably their darkness, and
 30 optionally their color, and terminating the roasting of the beans when the desired characteristic has been reached. In a presently preferred embodiment, the darkness of the beans is monitored with a reflectometer, or a spectrometer for measuring color, that views a flow or stream of coffee beans
 35 past a window that provides visual access to the interior of a roasting drum. A preferred embodiment employs a generally horizontally disposed, rotating roasting drum with interior vanes that extend radially from an outer periphery of the drum

towards its center and over the axial length of the drum. The vanes are curved so that, as the drum rotates, each vane picks up beans when it passes the low point of the drum and carries a quantity of beans upwardly. Once the generally radially oriented sides of the vanes become downwardly inclined, the beans will roll off and drop back to the bottom of the drum, thereby generating intermittent streams of beans at the window that can be observed by the spectrometer.

The reflectometer directs laser light having a wavelength of between about 600-800 nm onto the beans. In one preferred embodiment of the invention the specific wavelength of the laser is 680 nm and in another embodiment it is 750 nm. The reflectometer analyzes the reflected laser light to monitor the change in the darkness of the beans in real time.

Applicants have determined that a reliable parameter for determining when a desired finish, i.e. the taste and aroma, of a given type of coffee beans has been reached is the darkness of the beans, coupled with the manner in which the finish is attained in terms of roasting time and other roasting parameters. Principal parameters that influence the finish of the beans are the roasting speed, or time over which the beans are roasted, as well as the prevailing pressure in the drum, which will vary in accordance with atmospheric pressure variations.

Before retail roasting takes place, the ideal or desired roasting profile for each type of bean is experimentally determined at a central control station by a roastmaster generally in the manner in which roastmasters currently determine a desired profile for a given bean. Upon reaching this point in the experimental roasting process, the monitored roasting parameter or parameters, for example the darkness or spectral characteristics of the beans, e.g. in terms of the wavelength, or a range of wavelengths, as well as roasting time, roasting drum temperature variations, and the effects, if any, of atmospheric pressure variations, are electronically recorded and stored for later use.

Applicants have further determined that the change in darkness of the beans during roasting plays a role in the

finish of such beans when coffee is brewed from them. Contrary to past practice, when roasting was supervised by a roastmaster who subjectively determined when drum temperatures should be adjusted and roasting should be terminated, the present invention, relying on real time and objective monitoring of the roasting parameters, can adjust, again in real time, the roasting process to replicate the optimal roasting progression as previously determined by the roastmaster at each individual machine.

Thus, if the reflectometer of the roasting machine senses an accelerated or retarded darkening of the beans being roasted, adjustments to the roasting process, such as changing the hot roasting air temperature and/or flow rate, can be made in real time. This assures that the roasting process at each of the individual roasting machines precisely replicates the roasting process and profile that was previously performed by the roastmaster at the central control station during the sample roast, thus ensuring a constant and uniform bean finish. The established roasting parameters are recorded, stored and downloaded for subsequent use on the individual roasting machines. This represents a refinement, particularly advantageous for roasting coffee beans, that was not heretofore attainable because in the past the beans were roasted on the basis of the roastmaster's subjective observation and judgments concerning the progress of the roast without an objective monitoring and use of the parameters that determine the aroma of the roasted beans. Accordingly, the present invention assures a degree of consistent quality and aroma for roasted coffee beans that was heretofore simply unavailable.

A very important advantage of the present invention is that it permits one to replicate roasting results by using the darkness (or color) development time line for the beans being roasted to control the roasting drum temperature on a real-time basis throughout the roasting process to thereby precisely replicate the development and final taste and aroma profile of the beans. This is central to maintaining the consistency of the roasts and is not just a function of the

final darkness (or color) of the beans. How that darkness is attained also determines the final profile of the roasted product, e.g. the roasted beans, because the same darkness (or color) can be attained over a wide range of roasting times, which in turn depends on other parameters such as, for example, the roasting temperature. The profile of the roasted beans will vary greatly based on how the ultimate color was attained. For example, if beans are roasted too fast to attain a given darkness, the outside will be darker than the inside and the desired expansion of the bean will not be achieved, which impacts the profile of the roasted beans. Thus, the key to consistency in the profile is to roast the beans in the same way, time after time. This is accomplished with the reflectometer (or spectrometer) and maintaining the preestablished darkness (or color) development time line and parameters. In the past this was impractical, if not impossible, because there was no real-time color monitoring of the beans being roasted inside the roasting drum.

The roasting of beans for consumption (e.g. retail sale in stores or the brewing of coffee in espresso shops and the like) is conducted on site; for example in a store or an espresso shop, with individual, self-contained coffee roasting machines constructed in accordance with the invention. Each such roasting machine is networked with a computer at the central control station that has the necessary processors and memory to record and store the roasting profiles/recipes and parameters needed for controlling and terminating the bean roasting.

The stored roasting parameters for each variety of beans to be shipped to the in-store machines are downloaded to the computer that forms part of the in-store roasting machine. Thereafter, the beans can be roasted with the in-store machine simply by activating it, and selecting the bean type and quantity and the desired darkness of roast. Drawing on the stored recipe for the desired roast, the machine assures that the desired progression of the roast, as primarily determined from the change in darkness of the beans in real time, is adhered to. The roasting process continues until the beans

being roasted match the stored darkness for that type of beans and finish. When the desired color has been reached, the beans are removed from the roasting machine and cooled, e.g. on a cooling tray.

5 Typically, coffee retailers wish to have a variety of different beans, at times including different extents to which a given type of beans is roasted to provide flavor variations. For each bean type, the roasting parameters are established as is discussed above. In addition, if desired,
10 different degrees of roasting for any one or all bean types can be established to provide a choice of finishes that is available for a given type of bean. All of the needed parameters are downloaded to each roasting machine, and the roasting parameters for the selected bean type are then used
15 to control and terminate roasting when the selected finish for the chosen bean type has been reached.

 The initially established roasting parameters can be downloaded as easily to one as to many, individual roasters. The automatic roasting method of the present invention is
20 therefore ideally suited for use in a system that connects a central control station with multiple individual, geographically separate roasters. Since each roaster will use the same parameters (color development over time) for controlling and terminating the roast, the roasted coffee
25 beans will have a consistently uniform finish regardless where they are roasted and even though they are roasted without the supervision of a roastmaster.

 Thus, one aspect of the present invention is a method of roasting coffee beans by initially establishing the
30 varying degree over time to which the beans must be roasted to attain a desired finish during a sample roast. A measurable first parameter, which is indicative that the beans have been sufficiently roasted to yield the desired finish, is generated and stored. When a batch of green coffee beans is to be
35 roasted at one of the on-site roasting machines, the beans being roasted are monitored and a second parameter, which is compatible with the first parameter, is generated and compared with the first parameter. Upon detecting a match between the

first and second parameters, which, for example, are signals indicative of the change in darkness of the sample roast (at the central control station) and the beans being roasted on-site, the roasting is discontinued. In addition, the progress of the roasting operation, and in particular the change in darkness or development of the beans during roasting, is monitored in real time and compared to the darkness change encountered during the sample roast. If, during a subsequent on-site production roast, the darkness (or color) development of the beans deviates from that recorded during the sample roast, other roasting parameters, such as the hot roasting air temperature and/or the roasting air flow rate, are adjusted until the change in darkness corresponds to that established by the sample roast. This assures that the coffee bean finish obtained during the sample roast and judged to be optimal for the bean is precisely replicated during each production roast on each of the individual roasting machines that form part of the overall system.

For roasting coffee and other nuts and beans in the manner described in the preceding paragraphs, the present invention provides self-contained roasting machines that can be installed, for example, inside a retail establishment without requiring a vent or exhaust to the exterior of the room. Generally speaking, such a roasting machine includes a container having a bean inlet and a bean outlet for holding beans to be roasted. An air circulation system is operatively coupled with the container for flowing heated intake air over the beans and thereby roasting the beans. The heated air exits the container as used exhaust air that includes smoke and other pollutants. An air cleaning arrangement is operatively coupled with the air circulation system and located downstream of the container for removing substantially all particulates, smoke, and volatiles entrained in the used air as it flows through the container to provide substantially pollutant-free used air. An air cooling arrangement is operatively coupled with the air circulation system downstream of the container for cooling the used air to about room temperature. A used air discharge is located downstream of

the air cleaning and cooling arrangements for discharging at least a portion of the used air into an indoor environment substantially without adversely affecting the environment.

The intake air is preferably electrically heated to the desired roasting temperature to prevent the generation of relatively large volumes of combustion gases. The used air exiting the container is filtered to remove therefrom substantially all particulate matter of a size larger than about 1 micron, and before the used air is discharged into the surrounding store it is cooled to a temperature of no more than about 115°F (about 46°C) and preferably no more than about 100°F (about 38°C). When the filtered and cooled air is discharged, it will cause substantially no pollution and only negligible heating of air inside the store.

The global installation and operation of all individual roasting machines, and their interconnection and cooperation with the computer at the central roasting station, form another aspect of the invention, which, generally speaking, involves placing a roasting machine at each retail location or establishment and equipping each machine with a roasting drum or container for holding green coffee beans while they are being roasted, a hot air supply for heating the green beans to the roasting temperature, and an air removal system for directing used air away from the drum and cleaning it of substantially all debris, oil, smoke, and the like so that the used air can be discharged into the store atmosphere after it has passed the beans in the container without polluting it. During roasting, the beans in the drum are observed with a reflectometer or color analyzer and an output signal is generated therewith that reflects the observed darkness of the beans.

In a presently preferred embodiment, each roasting machine has an on-board computer to which the output signal is fed. At a central control station, the color and other parameters for each bean type that will yield the desired finish are determined, and corresponding control signals are generated, stored and downloaded to the computer of the individual, on-site roasting machines. During roasting at any

given roasting machine, the stored control signals are compared with the output signal generated by the instrument. If the compared signals do not match at any time during the roasting period, heat and air flow are automatically adjusted to achieve matching signals. When the compared final darkness (or color) signals match, a command is generated and used for terminating the roasting of the beans in the container.

In an alternative embodiment, on-board computers on each of the on-site roasting machines can be eliminated. Instead, a mainframe computer is set up at the central control station and is coupled to the roasting machines for running them directly from the central control station. This can help to prevent possible roasting errors due to malfunctioning, individual on-board computers.

BRIEF DESCRIPTION OF THE DRAWINGS

DETAILED DESCRIPTION OF THE INVENTION

20 The present invention is directed to the roasting of foodstuff and, in particular, to a coffee bean roasting method and apparatus having an internal air cleaning system that eliminates the need for exhausting roasting air to the exterior of buildings as well as for an afterburner to clean the roasting air before it is exhausted, that discharges clean air at or near room temperature that can be vented interiorly, and that assures consistent and uniform bean flavor, aroma and quality without the need for an attending roastmaster. As a result, roasting machines made in accordance with this invention can be placed inside stores and can be operated to provide daily roasted coffee beans that have consistent and uniform flavor. All this is achieved at a cost that is typically less than the cost of centrally roasting beans and distributing the roasted beans to retailers as is presently done. Although this application makes reference primarily to the roasting of coffee beans, the invention can be applied to roasting other foodstuffs such as other types of beans, seeds, nuts, kernels, and the like.

35 One aspect of the present invention is an automated method of roasting by computer monitoring and control without

the need for subjective judgment. Applicants have determined that the darkness or color of roasted beans is a reliable indicator of the development of the beans during roasting and the finish of coffee when brewed with such beans. A reflectometer (or spectrometer) is used to monitor the change in darkness (or color) of the beans during roasting. When the beans have reached a predetermined darkness, the reflectometer sends a signal to the computer to terminate the roasting. To enhance the quality and consistency of the roasted beans, other parameters that affect the ultimate finish can and should also be monitored and input into the computer to control roasting. For instance, the roasting speed, or the time over which the beans are roasted, the color or darkness development during the prescribed roasting time, the prevailing pressure in the roasting chamber, the roasting temperature, and the like can be monitored and used to determine when roasting should cease and/or what roasting parameters, such as heat, air flow or pressure, need to be adjusted.

Fig. 1 schematically illustrates a centrally controlled multi-station coffee roasting system 10 constructed and operated in accordance with the invention. It has a central control station 11 that includes a computer or master control server 12 and a plurality of, typically many, geographically dispersed individual roasting machines 14 networked with computer 12. Each of the individual roasting machines 14 includes an on-board computer with programmable logic controllers (PLCs) and/or a central processing unit (CPU) with on-board memory that is networked (telephonically or by wireless techniques) with the control server.

The control station includes a sample roasting machine 11a that is constructed substantially identical to the individual roasting machines 14 and with which a roastmaster performs sample roasts of different types of coffee beans to establish for each bean type one or more desired coffee roast profiles and finishes. Recordable parameters of relevant characteristics, primarily the darkness of the beans being sample-roasted and, secondarily, the roasting time, roasting

pressure, roasting temperature, and the like, are monitored and recorded. When the roastmaster has attained a specific darkness that he or she wish to replicate with the roasting machines 14 installed at the retail establishments, the
5 corresponding roasting parameters 11b are stored in the memory of master control server 12. The roastmaster will normally select a number of, say twelve, fifteen, or the like, different types of beans for which the needed roasting parameters are established and stored in the memory of the
10 central processor. All parameters, or at least those for beans that are to be roasted on one or more of the individual roasting machines that form part of the system, are then downloaded to a memory that forms part of the computer contained in each of the individual roasting machines. The
15 stored parameters are then available to control and terminate bean roasting on each individual machine, as is described in more detail below.

Alternatively, as already mentioned above, each individual roasting machine can be directly controlled with a
20 mainframe computer at the central control station, thereby eliminating the need for on-board computers on the individual roasting machines.

In addition to controlling the roasting of the beans by the individual roasting machines, master control server 12
25 can advantageously be used to monitor and assist in the management of the individual machines. For example, the inventory of green beans at the individual machines may be monitored, and fresh beans can then be automatically reordered from a suitable supplier to assure that sufficient beans are
30 always available when a low-inventory signal is received to assure an adequate bean supply at each individual machine. In addition, the machines, computers and the central computer can be used to monitor and record machine usage (for example on the basis of processed bean weight, roasting time, or the
35 like) as well as for billing, establishing profiles of bean types and/or aroma selection systemwide and at each individual roasting machine, and the like.

Along the same lines, the machines' computers and the central control server can be used for diagnostic purposes, for example to determine malfunctions or needed adjustments and the like for each individual machine, by
 5 providing access to the various roasting process monitors and sensors that form part of the roasting machines.

A major advantage of the centralized system 10 is that consistent, uniform, high quality bean roasts are assured. Further, since each roasting machine is on-site and
 10 can be activated whenever needed, the retailer can limit each roast so that no more than one-day's requirements for the beans are roasted, thereby assuring freshness and the best possible product for the consumer.

Referring to Figs. 2, 4 and 6, an individual
 15 roasting machine 14 made according to this invention has a rotary storage hopper 22 for storing and dispensing the foodstuff (e.g. the beans) to be roasted. The hopper is on top of and supported by a housing 24, and a roasting drum 44 is located inside of the housing. A bean handling system
 20 directs a selected bean type from hopper 22 into the drum and, after roasting, discharges the roasted beans onto a cooling tray 26 that protrudes horizontally from the housing. Also disposed on the inside of housing 24 is an air supply system that heats intake air to the desired roasting temperature,
 25 directs the heated air into the roasting drum, and from the drum directs the used or exhaust air through air cooling and air cleaning systems for the subsequent discharge of the used air at about room temperature into the atmosphere immediately surrounding the roasting machine. Thus, when installed in a
 30 supermarket, for example, the used air will be discharged into the interior of the surrounding building. To be acceptable for complete indoor installation and operation, the used air cleaning system removes all pollutants, such as white plume smoke, oily smoke, particulate matter, including chaff,
 35 volatiles, hydrocarbons, and the like, that are generated during roasting before the air is discharged from the machine.

Referring to Figs. 2 and 3, rotary hopper 22 has a cylindrical exterior, comprises, for example, sixteen sector-

shaped, upright compartments 30 arranged about the center of the hopper, and is rotatable about an upright shaft 30. A drive (not separately shown) incrementally advances the hopper about the upright shaft for indexing a bean discharge opening 36 at the bottom of each compartment with a green bean scale 42 of the roasting machine. A gate 116 keeps the compartment discharge openings 36 normally closed. When the opening of a given compartment is aligned with the scale and beans are to be transferred to the roasting drum, an actuator 117 under the control of the on-board computer of the roasting machine opens the gate so that the beans gravitationally flow onto the scale. When the desired quantity of beans has been transferred to the scale, the compartment gate is closed again. In one preferred embodiment of the invention, appropriate electronics 42a of the scale generate a weight-responsive electrical signal that is used to close the compartment gate when the preselected quantity of beans has been received on the scale. The hopper 22 includes a removable lid or cover 34 (Fig. 2) to protect the beans and provide access to the hopper compartment, for example for replenishing the beans in the compartments.

Referring to Figs. 5, 5a and 5b, the roasting of the beans takes place in a roasting drum 44 formed by concentric inner and outer drums 82, 84. The outer drum is cylindrical, stationary, sealed and has an upright front plate that is fixed, e.g. bolted to the frame. The outer drum forms a horizontal tubular chamber that extends rearwardly and, at the aft end of the outer drum, mounts an aft end plate 102 that defines a downwardly extending exhaust air outlet 90. In a presently preferred embodiment, the aft end of the outer drum and the forward end of the aft plate 102 form mating flanges that are held together with a conventional, schematically illustrated flange clamp 103 that permits quick removal of the clamp and disassembly of the drum.

The inner drum is perforated and has a rear wall 83 and a spider 85 with preferably three equally-spaced, radial legs that project inwardly from the inner drum, or two spiders 85 (the second being substituted for the rear wall 83). At

the axial center of the drum, the rear wall and spider(s) are fixed to a drum shaft 87 that is rotatable in shaft bearings 87a and 87b of front plate 104 and aft plate 103 of the outer drum. A pulley 89 driven by a motor (not separately shown) via a belt 89a rotates shaft 87 and therewith the inner drum in a given, say clockwise, direction (as viewed in Fig. 5a).

The inner drum further includes a plurality of elongated, generally longitudinally extending vanes 94 that project perpendicular to the inner drum wall and extend along a thread-like or helical line over the length of the inner drum. In the presently preferred embodiment, four such vanes are equally spaced about the inside of the inner drum, and the vanes extend through the sector-shaped openings formed by the radial legs of the spiders 85.

To remove beans that may become trapped in the annular space between the inner and outer drums, a spiral bean removal brush 91 can optionally be provided. It is made of heat-resistant material, e.g. stainless steel, extends helically over the length of the inner drum, and projects from the periphery thereof into the annular space to a point close to but slightly spaced from the inner surface of the outer drum 84. When the drum rotates, beans in the annular space between the drums are moved rearwardly by brush 91 and are ultimately discharged into the downwardly extending exhaust air outlet 90 (or into a bean collection receptacle or a separately provided bean removal conduit (not shown)).

Front plate 104 of roasting drum 44 has a tubular bean intake conduit 86 the open end of which is positioned immediately below a scale discharge opening 43 so that a fresh batch of green beans that has been weighed on the scale flows gravitationally into the drum for roasting by opening gate 43a following the weighing of the beans by the scale.

Roasted beans are removed from drum 44 via a bean outlet 88 in front plate 104 and via a discharge chute 110 onto cooling tray 26 by opening a drum discharge gate 122.

During roasting, the pressure inside the roasting drum exceeds atmospheric pressure, in a presently preferred embodiment by about 1.5 psi. To prevent the escape of the hot

roasting air, a gate - in the presently preferred embodiment of the invention, a butterfly disc 86a - is placed in the tubular conduit 86 between scale 42 and the interior of the drum. The butterfly disc includes a heat-resistant seal (not
 5 separately shown) that prevents the hot, pressurized air in the drum from escaping through the bean intake conduit. The butterfly disc remains closed at all times except when a fresh batch of green beans is to be gravitationally transferred from the scale to the drum interior. It is operated by a suitable
 10 drive (not separately shown) that is under the control of the computer of the roasting machine and is preferably synchronized with the activator (not shown) for scale gate 43a.

Similarly, bean discharge gate 122 is provided with
 15 a seal formed by a high temperature seal ring (not separately shown) that prevents the escape of hot, pressurized air from the interior of the drum when the gate is in its closed position. In the presently preferred embodiment of the invention, discharge gate 122 is hinged to the front plate 104
 20 along its upper edge and a linear drive (not separately shown) is provided for opening and closing the discharge gate. The drive for the discharge gate is also under the control of the computer of the roasting machine.

As is described in more detail below, the roasting
 25 of the beans is monitored with a reflectometer 108 (or a spectrometer for monitoring color) suitably mounted adjacent to front plate 104 with a holder 108a. The reflectometer directs a laser beam 109 through a window 98 in the front plate into the interior of the roasting drum.

30 Finally, rear plate 104 includes a hot roasting air inlet 92 that receives hot roasting air from an air intake conduit 92a.

Turning now to the manner in which fresh or green coffee beans are roasted in accordance with the invention,
 35 different types of green beans are placed into the hopper compartment 30 and an appropriate command is entered into an on-board computer 40 of the roasting machine which of the bean types is to be roasted. Its computer selects the appropriate

hopper compartment and activates the hopper drive (not shown in the drawings) to rotationally advance the hopper until the discharge opening 36 of the selected compartment is immediately above scale 42. Actuator 117 opens hopper gate 116 and green beans gravitationally drop onto the scale where they are weighed. When the desired weight of beans that is to be roasted has been received on the scale, the actuator, preferably via a signal from scale electronics 42a, closes the hopper gate and therewith terminates the transfer of beans.

The computer next activates the drive for bean inlet closure disc 86a to open it and also opens gate 43a in scale discharge opening 43, thereby permitting the beans to gravitationally flow from the scale via bean inlet 86 into the interior of inner drum 82. Thereafter intake disc gate 86a, as well as bean discharge gate 122, are closed, or maintained closed, to form a seal and prevent the escape of pressurized air from the interior of the drum through the bean intake or outlet.

The drum drive (not separately shown) is energized, to rotate in a drum 82 via pulley 89, and the air circulation system is activated to flow hot roasting air through hot air inlet 92 and the interior of the drum for discharge through exhaust or used air outlet 90, thereby bringing the beans to the roasting temperature.

The green beans introduced into the drum at the beginning of roasting initially rest at the bottom of the inner drum 82. When rotation commences, the radially inwardly extending vanes 94 pick up quantities of beans in a pocket defined by each vane and the portion of the inner drum adjoining the vane. As rotation of the drum continues, the beans in the pocket are lifted upwardly until the vane rises above the axis of shaft 87, at which point the side of the vane facing the pocket becomes downwardly inclined and the beans roll off the vane under the influence of gravity. The vanes are helically curved so that the sides thereof that form the pocket slope downwardly towards front plate 104 of the roasting drum. As a result, as the inner drum rotates, the beans in the pocket are also urged towards the front plate.

Thus, a stream of beans 95 from the elevated vane is intermittently formed in the vicinity of window 98 each time one of the vanes (with beans in the pocket) rises above the shaft centerline.

5 In the process, the beans become heated to the roasting temperature and as roasting time continues they undergo a gradual color change and darkening, which, for coffee beans, progresses from an initial gray-green color of the green beans to a light color giving the beans a bleached
10 appearance and then to increasingly dark shades of brown.

 The laser (not separately shown) of the reflectometer 108 is continuously or intermittently activated to direct laser light onto the stream of beans 95 on the inside of the drum. Laser light impinging on the beans is
15 reflected and the reflected light is sensed and analyzed by the reflectometer, for example by determining its wavelength. The desired darkness of the finished roasted beans (which was previously downloaded from the computer at the central control station) is stored in the memory of the on-board computer 40
20 of the roasting machine and compared with an output signal generated by the reflectometer that indicates the darkness of the beans in real time. When the signal from the reflectometer matches the stored signal in the on-board computer, roasting is terminated. In a preferred embodiment,
25 roasting is terminated by initially ceasing the heating of the roasting air flowing into the drum while continuing to rotate the inner drum (with bean outlet gate 122 closed) for about 30 to 45 seconds in a gradually cooling environment that enhances the finish that can be obtained with many types of beans.

30 In addition, while full heat roasting of the beans continues, the light/dark development of the beans inside the drum is monitored by reflectometer 108, which generates corresponding signals that are fed to the on-board computer. In a preferred embodiment, the memory of the on-board computer
35 includes light/dark level data that was generated during sample roasting at the central control station, typically as a function of roasting time and/or roasting temperature. Whenever the darkness level of the beans being roasted

deviates from the corresponding stored darkness level data, operating parameters, such as the roasting air temperature and/or roasting air flow rate, are adjusted to bring the darkness level of the beans being roasted in compliance with the stored darkness information in the memory of the on-board computer. In this manner, the test roast, which was performed to establish optimal roasting parameters for a given type of bean and/or roasting profile, is precisely replicated at each and every roasting operation on any and all of the individual roasting machines that are networked with the central computer at the central computer 12 at control station 11.

Once the beans are ready for discharge, the on-board computer activates the drive (not shown) for bean discharge gate 122 by moving it into its open position shown in Fig. 6. The continued rotation of inner drum 83, coupled with the helical shape of vanes 94 therein, gradually moves the beans in the direction of bean discharge opening 88, from where the roasted beans gravitationally drop onto cooling tray 26.

The cooling tray is preferably circular in shape (see Fig. 2) and includes one or more wiper arms 27 that slowly rotate with upright shaft 27a protruding from the tray. The arms gradually move the beans over the tray to facilitate their cooling, and, upon completion of the cooling, push the beans through a finish roasted bean discharge opening 124 to a suitable collection point or into a canister (not shown). The discharge opening is preferably located adjacent the periphery of the cooling tray, and the wiper arms are shaped so that they slowly direct the beans towards the periphery of the tray. The discharge opening is normally closed by a gate 125 that is opened via a suitable actuator (not shown) that is manually or automatically (by the on-board computer) opened after the beans have been sufficiently cooled. The cooling tray preferably includes perforations 26a (not shown and of a sufficiently small size to prevent beans from dropping through or becoming lodged in them) so that cooling air can be flowed over the beans on the tray to accelerate their cooling and, in accordance with an embodiment of the invention, to use the heat of the cooling beans for preheating fresh air before it

is heated for roasting a new batch of green beans that was placed into the drum.

Referring to Figs. 4 and 7-10, each individual roasting machine 14 includes an air supply or circulation system that comprises a blower 48 for generating an air flow through roasting drum 44 for the eventual discharge of the air from the machine. In a presently preferred embodiment of the roasting machine in which 6-lb. batches of green beans are roasted in about twelve minutes, the blower has a 2-1/2 HP motor, generates a pressure rise of about 1.5 psi at about 50 cfm through the air circulation system, and heats the air, as a result of the compression of the air, by about 30°F-50°F (about 17°C-28°C).

As is best seen in Fig. 8, the air circulation system preferably receives fresh intake air that was preheated by flowing it over just-roasted, still-hot beans on cooling tray 26 and through perforations 26a therein to thereby reduce the overall energy consumption of the machine. Since the intake air may pick up particulates and white plume smoke as it passes over the roasted beans on the cooling tray, a prefilter 50 is provided to remove such smoke and debris before the air enters fan 48. Filter 50 preferably comprises a .3-micron HEPA filter with a relatively low pressure drop so that it can remove the white plume smoke and smoke particulates from the intake air.

Fan 48 is coupled to a heat exchanger 54, which preheats the air from the fan. The structure and operation of the heat exchanger is discussed in more detail below. The preheated air flows from the heat exchanger 54 to a heater 56 for heating it to the desired roasting temperature. The heater 56 is preferably a flow-through electric duct (tubular) heater 56 capable of heating the incoming air from about 120°F (about 49°C) and at 50 cfm to the roasting temperature, e.g. about 500°F (about 260°C). From the heater the roasting air flows via a conduit 92a and past roasting air inlet 92 into and through the roasting drum from which it exits via used air exit 90.

In the drum, the green beans give off particulates, including chaff, as well as white plume smoke, oily smoke, volatiles, hydrocarbons, and the like, which are carried out of the roasting drum by the air. To enable the discharge of the air into the indoor environment surrounding each individual roasting machine 14, the used roasting air must be cleaned and cooled before it can be discharged.

Chaff, an onionskin-like husk byproduct that is flaked off the beans in the roasting drum, is removed in a chaff collector 60 located downstream of and coupled to roasting drum 44. The chaff collector 60 comprises a vortex particulate separator (not shown) that captures the chaff and lets the air through. The chaff collecting tray is periodically removed and cleaned as needed.

A primary filter 64 is coupled to the chaff collector 60 via a conduit (not shown) for the removal of tars and chaff fines. In one embodiment, the primary filter 64 is made of superfine steel wool media. In another embodiment, a prefilter 62 made from superfine 30 micron media is positioned upstream of the primary filter to remove fines from the air flow and prevent a premature plugging of the filter by the fines.

From the primary filter 64, the used air flows to heat exchanger 54 for cooling. In the presently preferred embodiment, the heat exchanger is formed of a plurality of heat pipes (not shown) coupled to cooling fins. The relatively cool intake air flows in one direction over one end of the heat pipe array and the relatively hot exhaust air, separated from the cool air by a wall, is conveyed in the opposite direction over the other end of the heat pipe array. Heat from the hot exhaust air is transferred via the heat pipe array to the cool intake air flowing from the blower 48 to preheat it before it enters heater 56 and thereby improve the energy efficiency of the roasting machine. The heat exchanger is about 80% efficient and typically cools the air exhaust air from about 350° (about 177°C) to 100°F (about 38°C).

Alternatively, the heat exchanger can also be formed of double concentric counterflow hoses or pipes. In that

case, an outer tube 66 conveys the relatively cool intake air in one direction and an inner tube 68 conveys the relatively hot exhaust air in the opposite direction, or vice versa.

Heat from the exhaust air is transferred via inner tube 68 to the cool intake air flowing towards fan 48 to thereby preheat it before it enters heater 56 to thereby improve the energy efficiency of the roasting machine.

The air is then cooled to about 100°F (about 38°C) in an aftercooler 72 disposed downstream of and receiving the air from the heat exchanger 54. It typically cools the air from about 350°F (about 177°C), the exit temperature at the main heat exchanger, to about 100°F (38°C). In the illustrated alternative embodiment, aftercooler 72 employs a finned-tube heat sink of a serpentine configuration with sufficient length to achieve the desired temperature drop.

A high efficiency particulate accumulator ("HEPA") filter 74 is coupled to the heat exchanger and a carbon filter 76 is coupled to the HEPA filter 74. The HEPA filter 74 is preferably a .3-micron media that captures white plume smoke and particles as small as 1/2 micron with a 99+% efficiency. The carbon filter 76 employs activated carbon that filters VOCs and hydrocarbons (SO₂, NO₂, etc.) in the used air stream before it is discharged from the machine. The carbon filter 76 can be used to control the amount of VOCs, and therewith the coffee aroma that emanates from the roasting machine.

Thus, and as is illustrated in Fig. 8, the intake air enters the prefilter 50, which filters out smoke and/or debris in the air. The fan 48 produces a flow of the air that traverses the entire roasting machine in no more than about 1 second and, preferably, in as little as about 1/4 second while the air is heated from ambient at intake to about 500°F (about 260°C) for roasting and is then cooled again to about room temperature (approximately 100°F, 38°C) at discharge. The hot air therefore flows through the roasting drum 44 in a continuous, high temperature flow to thereby effectively roast the beans.

Referring to Fig. 9, sensors are employed throughout each individual roasting machine 14 for monitoring and controlling the roasting of the beans.

For example, a temperature gauge or thermometer 132 and a pressure gauge 134 are disposed at the inlet of the prefilter 50 to measure the inlet air temperature and pressure. A pressure gauge 136 measures the inlet pressure of the fan 48 and another pressure gauge 138 measures the outlet pressure of the fan. The temperature of the air at the inlet and outlet of the heat exchanger 54 is measured with temperature gauges 142 and 144. A further temperature gauge 146 at the outlet of the heater 56 measures the roasting temperature of the air. A thermometer 150 and a pressure gauge 152 can be provided to measure the temperature and pressure in the roasting chamber 44. A pair of pressure gauges 154, 156 at the inlet and outlet of the smoke filter 64 measure the pressure drop across it. The exhaust air temperature drop across the heat exchanger 54 is measured with a pair of thermometers 158, 162 disposed at the inlet and outlet of the heat exchanger. Another thermometer 164 provided at the outlet of the aftercooler 72 measures the temperature drop caused by it. A pressure gauge 168 at the inlet of the HEPA filter 74 measures the inlet pressure. A pressure gauge 170 at the outlet of the HEPA filter 74 measures the outlet pressure of the HEPA filter 74 and the inlet pressure of the carbon filter 76. A pressure gauge 172 at the outlet of the carbon filter 76 measures the outlet pressure. If desired, flow rates at various points of the system may be measured with appropriate flow gauges.

As discussed above, while it is preferred to use a reflectometer to monitor the darkness of the beans during roasting, spectrometers can be used instead for measuring the color of the beans. Spectrometers or colorimeters capable of detecting colors that can be used with the present invention are known. For example, U.S. Patent No. 5,684,582 issued November 4, 1997 to Eastman et al. and U.S. Patent No. 5,504,575 issued April 2, 1996 to Stafford, which are incorporated by reference herein, disclose useable

spectrometers. The patent to Stafford specifically discusses the use of a spectrometer to monitor the color of food products to ensure a uniform color for the consumer.

On-board roasting computer software of the roasting machine 14 serves, among others, the following functions:

1. Receiving in-store operator roasting requests and initiating roasting sequence, including preheating system check, upon request.
- 10 2. Rotating the rotary hopper to the desired green beans position and releasing a correct quantity of the beans into the scale funnel 42.
3. Releasing the beans from the scale funnel 42 into the roasting chamber 44.
- 15 4. Roasting the beans to the appropriate recipe established at central control station 11 and, if desired, modifying the recipe with real-time barometric input.
- 20 5. Guiding roasting development and final roast degree (darkness) by real-time input from the laser reflectometer 108.
- 25 6. Starting the cooling tray sweep arm and discharging the roasted beans from the roasting chamber 44 to the cooling tray 26 when the spectrometer 108 determines that roasting is complete.
7. Stirring/cooling the finished beans on the cooling tray 26 and discharging them into the discharge container when ready.
- 30 8. Starting loading/roasting the next batch upon discharge of the previous batch to the cooling tray 26.

The block diagram in Fig. 10 illustrates a roasting system that comprises the combined configuration of the bean handling system of Fig. 7 and the internal air control system of Fig. 8. The arrows illustrate the bean flow and the air flow. The point of intersection between the two flows is located at the roasting chamber 44, in which the heated air is

used to roast the beans. In this embodiment, the intake air comes from and the exhaust air is released into the surrounding environment at a temperature that is close to room temperature. By circulating air taken from outside
5 surroundings of the roasting apparatus 20 and releasing it back into the surroundings, the internal air control system is an open-loop system.

An alternative is a closed-loop air circulation system that comprises substantially the same components as the
10 open-loop system. The primary difference is that only a small proportion, e.g. 20% of the used air, is discharged to the atmosphere, while the remainder, after thorough cleaning, is recirculated through the roasting machine. The earlier
15 discussed HEPA and charcoal filters 74, 76 are effective only at relatively low temperatures of about 100°F (about 38°C). To prevent the need for cooling the used air to such low temperatures in a closed-loop air circulation system while still removing white plume smoke, VOCs, hydrocarbons, and the like, a catalytic converter (not shown) may be used instead of
20 such filters. With a catalytic converter the cleaned air can be recirculated to the fan of the machine at significantly higher temperatures, which, in turn, reduces the energy consumption of the machine. Water removed from the green
25 beans during roasting and entrained in the recirculating used roasting air is discharged from the system with the earlier mentioned release of a small, e.g. 20%, proportion of the used air.

WHAT IS CLAIMED IS:

1 1. A method of roasting a food product comprising
 2 the steps of establishing the degree to which the product must
 3 be roasted to attain a desired aroma; generating a measurable
 4 first parameter which is indicative that the product has been
 5 sufficiently roasted to yield the desired aroma; storing the
 6 first parameter; roasting fresh product at a roasting
 7 temperature; monitoring a second parameter which is compatible
 8 with the first parameter and is generated by the fresh product
 9 during roasting; and, upon detecting a match between the first
 10 and second parameters, discontinuing the roasting step.

1 2. A method according to claim 1 wherein the first
 2 parameter is one of the color and darkness of the product and
 3 the second parameter is one of the color and darkness of the
 4 fresh product during the roasting step.

1 3. A method according to claim 2 including
 2 adjusting the step of discontinuing the roasting of the fresh
 3 product as a function of at least one of the roasting
 4 temperature and atmospheric pressure.

1 4. A method according to claim 1 wherein the step
 2 of monitoring comprises making a spectral analysis of the
 3 fresh product during the roasting step.

1 5. A method according to claim 4 wherein the step
 2 of making a spectral analysis comprises directing a laser beam
 3 onto the fresh product during the roasting step.

1 6. A method according to claim 5 wherein the laser
 2 beam has a wavelength in the range of between about 600 to 800
 3 nm.

1 7. A method according to claim 1 including the
 2 steps of providing a multiplicity of different product types,
 3 establishing and storing the first parameter for each product

4 type, prior to the roasting step selecting one of the
5 multiplicity of product types for roasting; and wherein the
6 step of discontinuing is carried out when a match between the
7 first parameter for the selected product type and the second
8 parameter match.

1 8. A method according to claim 7 including the
2 step of establishing a plurality of first parameters for at
3 least one of the multiplicity of product types, each of which
4 defines a different degree to which the product must be
5 roasted to attain correspondingly differing desired aromas;
6 prior to the roasting step selecting one of the plurality of
7 first parameters for the at least one product type; and
8 wherein the step of discontinuing is performed when the second
9 parameter matches the selected one of the first parameters.

1 9. A method according to claim 1 wherein the
2 roasting step comprises flowing heated air over the fresh
3 product, and including the steps of removing substantially all
4 pollutants from the air downstream of the fresh product being
5 heated, cooling the air downstream of the fresh product to
6 substantially room temperature, and thereafter exhausting the
7 cooled air into a room of a building.

1 10. A method according to claim 1 wherein the step
2 of roasting includes flowing heated air over the fresh
3 product, and including the steps of filtering substantially
4 all pollutants from the heated air following the roasting
5 step, thereafter reheating and recirculating a major portion
6 of the substantially pollutant-free air over the fresh product
7 to thereby continue the roasting step; and discharging a minor
8 portion of the filtered air prior to reheating and
9 recirculating the major portion of the air.

1 11. A method of automatically roasting coffee beans
2 to attain a predetermined, desired coffee aroma comprising the
3 steps of roasting a sample of the beans to a degree at which
4 coffee made with the beans exhibits the desired aroma; sensing

5 one of a color and a darkness of the beans when they have
 6 reached the degree of roasting and from the sensed color or
 7 darkness generating a first parameter which is indicative of
 8 the sensed color or darkness of the bean sample; storing the
 9 first parameter; thereafter roasting fresh beans; monitoring
 10 one of the color or darkness of the fresh beans being roasted
 11 and generating a second parameter which is indicative of a
 12 color or darkness of the fresh beans; comparing the first and
 13 second parameters during roasting of the fresh beans; and
 14 terminating the roasting of the fresh beans when the first and
 15 second parameters match.

1 12. A method according to claim 11 wherein the step
 2 of roasting the fresh beans comprises flowing heated air over
 3 the fresh beans; and including the steps of cleaning the
 4 heated air after it has passed the fresh beans so that the air
 5 is substantially pollutant-free; cooling the air after it has
 6 passed the fresh beans to about room temperature; and
 7 discharging the pollutant-free, room temperature air.

1 13. A method according to claim 12 wherein the
 2 steps of roasting the fresh beans and heating, cleaning and
 3 cooling the air are performed in a substantially closed room
 4 frequented by humans, and wherein the step of discharging the
 5 air comprises discharging the air into the room.

1 14. Apparatus for roasting coffee beans comprising
 2 a container having a bean inlet and a bean outlet for holding
 3 beans to be roasted; an air circulation system operatively
 4 coupled with the container for flowing heated air over the
 5 beans and thereby roasting the beans, the heated air exiting
 6 the container as used air; an air cleaning arrangement
 7 operatively coupled with the air circulation system and
 8 located downstream of the container for removing substantially
 9 all particulates, smoke and volatiles entrained in the used
 10 air as it flows through the container to provide substantially
 11 pollutant-free used air; an air cooling arrangement
 12 operatively coupled with the air circulation system downstream

13 of the container for cooling the used air to about room
14 temperature; and a used air discharge located downstream of
15 the air cleaning and cooling arrangements for discharging at
16 least a portion of the used air into an indoor environment
17 substantially without adversely affecting the environment.

1 15. Apparatus according to claim 14 wherein the air
2 circulation system includes a flow divider returning a major
3 portion of the used air to the circulation system and
4 discharging a minor portion of the used air into the
5 environment.

1 16. Apparatus according to claim 15 wherein the air
2 cooling arrangement is operatively coupled with the air
3 divider so that only the minor portion of the air is cooled to
4 about room temperature.

1 17. Apparatus according to claim 16 wherein the
2 cooling arrangement is operative so that the major portion of
3 the used air which is being returned to the circulation system
4 has a temperature substantially higher than room temperature.

1 18. Apparatus according to claim 14 wherein the
2 used air discharge discharges all used air into the
3 environment.

1 19. Apparatus according to claim 14 wherein the
2 container comprises an inner drum rotatable about a generally
3 horizontal axis and an outer, stationary drum disposed about
4 the inner drum.

1 20. Apparatus according to claim 19 wherein the
2 inner drum has an open axial end and the outer drum has an end
3 plate overlying the open end of the inner drum, the end plate
4 including a bean inlet for introducing fresh beans into the
5 inner drum for subsequent roasting and an outlet for removing
6 roasted beans from the inner drum.

1 21. Apparatus according to claim 20 wherein the end
2 plate includes a window for viewing an interior of the inner
3 drum from an exterior of the outer drum, and wherein the inner
4 drum includes radially inwardly projecting vanes extending
5 generally in a longitudinal direction of the inner drum and
6 being shaped so that the vanes form intermittent streams of
7 beans being roasted and flowing past the window when the inner
8 drum is rotated and beans are disposed therein.

1 22. Apparatus according to claim 21 including a
2 reflectometer mounted proximate the window for determining a
3 darkness of the beans flowing in the intermittent stream of
4 beans past the window.

1 23. Apparatus according to claim 22 including means
2 for removing the beans from the drum through the bean outlet,
3 and a controller operatively coupled with the reflectometer
4 and the bean outlet for initiating a removal of the roasted
5 beans from the inner drum when the reflectometer senses that
6 the beans in the drum have reached a desired darkness.

1 24. Apparatus according to claim 20 including a
2 fresh bean storage hopper having a plurality of fresh bean
3 storage compartments, a conveyor for directing beans from the
4 compartments to the bean inlet, and means for transporting
5 beans from a selected one of the compartments to the conveyor.

1 25. Apparatus according to claim 24 wherein the
2 transporting means comprises an opening in each compartment
3 and an openable closure for each opening so that beans can be
4 transferred from a selected one of the compartments to the
5 conveyor by opening the closure.

1 26. Apparatus according to claim 24 wherein the
2 conveyor comprises a conduit which gravitationally transfers
3 the beans from the opening in the selected one of the
4 compartments to the bean inlet.

1 27. Apparatus according to claim 26 wherein the
2 hopper is movable relative to the bean conduit for positioning
3 the opening of each compartment relative to the conduit to
4 gravitationally flow fresh beans from the selected one of the
5 compartments to the conduit.

1 28. Apparatus according to claim 27 including a
2 scale for weighing an amount of beans to be transferred from a
3 selected one of the compartments to the conduit, wherein the
4 conduit has an intake end remote from the bean inlet, and
5 wherein the scale is positioned between the opening in the
6 selected hopper compartment and the intake end of the conduit
7 so that the amount of beans can be gravitationally fed into
8 the intake end of the conduit.

1 29. Apparatus according to claim 20 including a
2 roasted bean cooling tray arranged to receive roasted beans
3 removed from the inner drum via the bean outlet in the end
4 plate.

1 30. Apparatus according to claim 29 including a
2 wiper operatively coupled with the cooling tray for moving the
3 roasted beans over the tray and to a cooled, roasted bean
4 collector.

1 31. Apparatus according to claim 30 including means
2 for flowing a roasted bean cooling air stream past the beans
3 on the cooling tray.

1 32. Apparatus according to claim 31 wherein the air
2 circulation system includes a fresh air intake, and wherein
3 the fresh air intake is operatively coupled with the cooling
4 air stream flowing means for preheating fresh air entering the
5 air circulation system with heat obtained from the roasted
6 beans on the cooling tray.

1 33. Apparatus according to claim 32 wherein the
2 roasted beans on the tray give off white plume smoke, and

3 including an air filter in a vicinity of the air intake of the
4 air circulation system for removing white plume smoke and
5 particulates from the air flow entering the air circulation
6 system.

1 34. Apparatus according to claim 33 wherein the
2 filter comprises a stainless steel mesh filter having a mesh
3 size sufficient for removing particles having a size larger
4 than about a 1/2-micron size from the air entering the air
5 circulation system.

1 35. Apparatus according to claim 14 wherein the air
2 circulation system includes means for heating the air flowing
3 therein to a roasting temperature upstream of the container.

1 36. Apparatus according to claim 35 wherein the
2 heater includes a combustion-free main heater for heating the
3 air to the roasting temperature and an auxiliary heater for
4 preheating the air upstream of the main heater.

1 37. Apparatus according to claim 36 wherein the
2 auxiliary heater includes a heat exchanger for transferring
3 heat from used air exiting the container to cool air flowing
4 to the main heater and comprises first and second air flow
5 conduits separated by a common wall.

1 38. Apparatus according to claim 36 including an
2 air blower in the air circulation system for generating the
3 air flow therein, and wherein the blower comprises a portion
4 of the auxiliary preheater and heats air by increasing a
5 pressure thereof.

1 39. Apparatus according to claim 36 including a
2 cooling tray positioned for receiving roasted beans from the
3 container, and wherein the auxiliary preheater includes means
4 for flowing cool air over the roasted beans on the cooling
5 tray and thereafter into an intake of the air circulation
6 system.

1 40. Apparatus according to claim 36 including means
2 operatively coupled with the air circulation system for
3 reducing a temperature of used air exiting the container to
4 about room temperature upstream of the air discharge.

1 41. Apparatus according to claim 40 wherein the air
2 temperature reducing means comprises a counterflow heat
3 exchanger for transferring heat from the used air exiting the
4 container to cool air in the circulation system before the
5 cool air reaches the main heater.

1 42. Apparatus according to claim 41 wherein the
2 used air exits the heat exchanger at a temperature
3 significantly above room temperature, and including a heat
4 sink between the heat exchanger and the air discharge for
5 lowering the temperature of the used air to about room
6 temperature.

1 43. Apparatus according to claim 35 wherein the air
2 cleaning arrangement comprises a main filter for removing
3 smoke from used air exiting the container.

1 44. Apparatus according to claim 43 wherein the
2 main filter comprises a mesh filter having a mesh size of .3
3 microns.

1 45. Apparatus according to claim 43 wherein the air
2 cleaning arrangement includes a HEPA filter downstream of the
3 main filter for removing white plume smoke from the used air.

1 46. Apparatus according to claim 45 wherein the
2 HEPA filter is a mesh filter having a mesh size of about 1
3 micron.

1 47. Apparatus according to claim 45 wherein the air
2 cleaning arrangement includes a screen collector for removing
3 bean chaff from the used air upstream of the main filter.

1 48. Apparatus according to claim 47 wherein the
2 chaff collector is a mesh filter having a mesh size of no more
3 than about 30 microns.

1 49. Apparatus according to claim 47 including a
2 heat exchanger located downstream of the main filter for
3 transferring heat from the used air to relatively cool air
4 flowing through the circulation system upstream of the heater.

1 50. Apparatus according to claim 49 including a
2 final filter located downstream of the heat exchanger and
3 upstream of the air discharge for removing volatile organic
4 compounds (VOCs) and hydrocarbons from the used air before it
5 reaches the air discharge.

1 51. Apparatus according to claim 50 wherein the
2 final filter comprises an activated carbon filter.

1 52. Apparatus according to claim 51 including an
2 air cooler in the air circulation system located downstream of
3 the heat exchanger and upstream of the HEPA filter and the
4 activated carbon filter for lowering a temperature of the used
5 air to no more than about 115°F.

1 53. A method for roasting coffee beans inside a
2 store comprising the steps of placing fresh beans inside a
3 container; electrically heating air to a desired roasting
4 temperature; flowing the heated air through the container and
5 about the fresh beans therein to thereby roast the beans;
6 filtering hot air exiting the container to remove therefrom
7 substantially all oily and white plume smoke, volatile organic
8 compounds, hydrocarbons, and other particulate subject matter
9 of a size larger than about 1 micron so that, thereafter, the
10 air is substantially pollutant-free; cooling used air exiting
11 the container to a temperature of no more than about 115°F;
12 and thereafter discharging the filtered and cooled air
13 directly into the store, whereby the discharged air will cause
14 substantially no pollution of air inside the store.

1 54. A method according to claim 53 including the
2 step of spectrally analyzing the beans with an instrument
3 generating an output signal which is a function of one of the
4 color and the darkness of the beans in the container; and
5 removing the beans from the container to thereby terminate
6 their roasting when the output signal indicates that the beans
7 have reached a predetermined color or darkness.

1 55. A method according to claim 53 wherein the step
2 of filtering comprises providing a plurality of flow-through
3 filters; flowing the used air successively through the filters
4 to remove substantially all pollutants therefrom, monitoring
5 air pressure drops across each filter, removing and cleaning
6 each filter when an associated corresponding air pressure drop
7 exceeds a predetermined value; and thereafter reinstalling the
8 cleaned filter.

1 56. A method for uniformly roasting coffee beans at
2 a plurality of geographically separate locations comprising
3 the steps of placing a roasting machine at each location;
4 equipping each roasting machine with a roasting container for
5 holding fresh beans while they are being roasted, a hot air
6 supply for heating the fresh beans to a roasting temperature,
7 and an air removal system for directing used air away from the
8 container and removing therefrom substantially all debris,
9 smoke, oil, and the like so that air can be discharged into
10 the atmosphere after it has passed the beans in the container
11 without polluting it; observing the beans in the container
12 during roasting with a reflectometer and therewith generating
13 an output signal which reflects the observed darkness of the
14 beans; providing each roasting machine with a computer
15 including a memory; feeding the output signal to the computer;
16 at a central control station determining an optimal darkness
17 for each bean type that will be roasted by the roasting
18 machines; at the control station generating a control signal
19 which reflects the optimal darkness of each roasted bean type;
20 downloading the control signal from the central control
21 station to the computer of each roasting machine; during

roasting at any given roasting machine comparing the control signal stored in the associated memory with the output signal generated by the instrument; when the compared signals match, generating a command signal; and using the command signal to terminate the roasting of the beans in the container.

57. The method according to claim 56 including the steps of keeping an inventory of fresh beans proximate each roasting machine; monitoring the size of the fresh bean inventory; generating a low-inventory signal when the fresh bean inventory drops below a predetermined level; transmitting the inventory control signal to the central control station; and transferring additional fresh beans to the roasting machine which generated the low-inventory signal upon receipt thereof at the control station.

58. A method according to claim 56 wherein each roasting machine has a plurality of different fresh bean types which can be roasted; and including the steps of generating an optimal darkness signal for each bean type at the control station; downloading each darkness signal to the computers of the roasting machines of the system; and, during roasting at any given one of the roasting machines, comparing the output signal from the instrument with the stored darkness signal which corresponds to the bean type being roasted in the container.

59. A method for treating matter that releases atmosphere polluting materials when subjected to heat, the method comprising the steps of providing a chamber including an inlet and an outlet, placing the material in the chamber, generating the air flow and directing it along an upstream flow path through the inlet into the chamber, heating the air flow in the upstream flow path to form a hot air flow, and directing the hot air flow through the inlet into the chamber, whereby materials released by the matter become entrained in the hot air flow, thereby generating a polluted air flow; directing the polluted air flow through the outlet into a

12 downstream flow path; in the downstream flow path removing
13 most of the materials from the polluted air flow to thereby
14 generate a clean air flow which can be discharged into the
15 atmosphere without causing substantial air pollution; cooling
16 the air flow in the downstream flow path to a temperature
17 suitable for release of the air into a closed environment; and
18 limiting the flow time for the air flow from an upstream end
19 of the upstream path to a downstream of the downstream path to
20 substantially no more than about 1 second.

1 60. A method according to claim 59 wherein the step
2 of cooling comprises the step of transferring a major portion
3 of heat energy in the air flow through the downstream flow
4 path to the air flow in the upstream flow path.

1 61. A method according to claim 60 wherein the step
2 of limiting comprises the step of limiting the flow time to no
3 more than about 1/4 second.

ROASTING SYSTEM

ABSTRACT OF THE DISCLOSURE

5 An apparatus and method of roasting foodstuff such
as coffee beans employ a roasting chamber for roasting the
beans. An air circulation system operatively coupled with the
chamber flows heated air over the beans and thereby roasts the
beans, and an air cleaning arrangement is operatively coupled
10 with the air circulation system and located downstream of the
chamber for removing substantially all particulates, smoke and
volatiles entrained in the used air as it flows through the
container and into the air cleaning arrangement to provide
substantially pollutant-free used air. The circulation system
15 uses atmospheric air and heats, cleans and cools it within as
little as 1/4 second. Sensors and a electronic controller are
provided to monitor various parameters in the roasting
apparatus and control the roasting characteristics. The
darkness and/or color of the beans during roasting is
monitored to ensure proper roasting. The roasting in roasting
20 machines at a plurality of geographically separate locations
is controlled by equipping each roasting machine with a
computer with memory and providing a central control station
for downloading control signals to the computer to control
roasting.

DECLARATION AND POWER OF ATTORNEY

As a below-named inventor, I declare that:

My residence, post office address and citizenship are as stated below next to my name; I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural inventors are named below) of the subject matter which is claimed and for which a patent is sought on the invention entitled: ROASTING SYSTEM, the specification of which x is attached hereto or was filed on as Application No. and was amended on (if applicable).

I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above. I acknowledge the duty to disclose information which is material to the examination of this application in accordance with Title 37, Code of Federal Regulations, Section 1.56. I claim foreign priority benefits under Title 35, United States Code, Section 119 of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign application for patent or inventor's certificate having a filing date before that of the application on which priority is claimed.

Prior Foreign Application(s)

Country	Application No.	Date of Filing	Priority Claimed Under 35 USC 119
			Yes <u> </u> No <u> </u>
			Yes <u> </u> No <u> </u>

I hereby claim the benefit under Title 35, United States Code § 119(e) of any United States provisional application(s) listed below:

Application No.	Filing Date
60/065,083	November 11, 1997

I claim the benefit under Title 35, United States Code, Section 120 of any United States application(s) listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application in the manner provided by the first paragraph of Title 35, United States Code, Section 112, I acknowledge the duty to disclose material information as defined in Title 37, Code of Federal Regulations, Section 1.56 which occurred between the filing date of the prior application and the national or PCT international filing date of this application:

VERIFIED STATEMENT (DECLARATION) CLAIMING SMALL ENTITY STATUS
(37 CFR 1.9(f) and 1.27(b)) - SMALL BUSINESS CONCERN

Applicant or Patentee Roger A. Allington and Philip A. Torbet
 Serial No.: _____ Filing Date: _____
 Patent No.: _____ Issued: _____
 For: ROASTING SYSTEM

I hereby declare that I am

- ☐ the owner of the small business concern identified below:
☒ an official of the small business concern empowered to act on behalf of the concern identified below:

NAME OF CONCERN Fresh Roast Systems, Inc.
 ADDRESS OF CONCERN 1225 N. McDowell Boulevard, Petaluma, CA 94954

I hereby declare that the above-identified small business concern qualifies as a small business concern as defined in 13 CFR 121.3-18, and reproduced in 37 CFR 1.9(d), for purposes of paying reduced fees under section 41(a) and (b) of Title 35, United States Code, in that the number of employees of the concern, including those of its affiliates, does not exceed 500 persons. For purposes of this statement, (1) the number of employees of the business concern is the average over the previous fiscal year of the concern of the persons employed on a full-time, part-time or temporary basis during each of the pay periods of the fiscal year, and (2) concerns are affiliates of each other when either, directly or indirectly, one concern controls or has the power to control the other, or a third party or parties controls or has the power to control both.

I hereby declare that rights under contract or law have been conveyed to and remain with the small business concern identified above with regard to the invention, entitled ROASTING SYSTEM by inventor(s) Roger A. Allington and Philip A. Torbet described in

- ☒ the application filed herewith
☐ application Serial No. _____, filed _____
☐ Patent No. _____, issued _____

If the rights held by the above-identified small business concern are not exclusive, each individual, concern or organization having rights to the invention is listed below* and no rights to the invention are held by any person, other than the inventor, who would not qualify as an independent inventor under 37 CFR 1.9(c) if that person made the invention, or by any concern which would not qualify as a small business concern under 37 CFR 1.9(d), or a nonprofit organization under 37 CFR 1.9(e).

*NOTE: Separate verified statements are required from each named person, concern or organization having rights to the invention averring to their status as small entities. (37 CFR 1.27)

FULL NAME _____
 ADDRESS _____

☐ INDIVIDUAL ☐ SMALL BUSINESS CONCERN ☐ NONPROFIT ORGANIZATION

FULL NAME _____
 ADDRESS _____

☐ INDIVIDUAL ☐ SMALL BUSINESS CONCERN ☐ NONPROFIT ORGANIZATION

I acknowledge the duty to file, in this application or patent, notification of any change in status resulting in loss of entitlement to small entity status prior to paying, or at the time of paying, the earliest of the issue fee or any maintenance fee due after the date on which status as a small entity is no longer appropriate. (37 CFR 1.28(b)).

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under section 1001 of Title 18 of the United States Code, and that such willful false statements may jeopardize the validity of the application, any patent issuing thereon, or any patent to which this verified statement is directed.
